

COMP9517: Computer Vision

Motion

Introduction

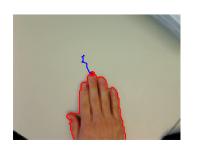

Adding the time dimension to the image formation

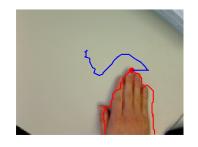

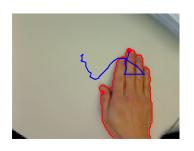

Introduction

 A changing scene may be observed and analysed via a sequence of images

Introduction

- Changes in an image sequence provide features for
 - Detecting objects that are moving
 - Computing trajectories of moving objects
 - Performing motion analysis of moving objects
 - Recognising objects based on their behaviours
 - Computing the motion of the viewer in the world
 - Detecting and recognising activities in a scene

Applications

Motion-based recognition

Human identification based on gait, automatic object detection

Automated surveillance

Monitoring a scene to detect suspicious activities or unlikely events

Video indexing

Automatic annotation and retrieval of videos in multimedia databases

Human-computer interaction

Gesture recognition, eye gaze tracking for data input to computers

Traffic monitoring

Real-time gathering of traffic statistics to direct traffic flow

Vehicle navigation

Video-based path planning and obstacle avoidance capabilities

Scenarios

- Still camera
 Constant background with
 - Single moving object
 - Multiple moving objects

- Moving camera
 Relatively constant scene with
 - Coherent scene motion
 - Single moving object
 - Multiple moving objects

Topics

Change detection

Using image subtraction to detect changes in scenes

Sparse motion estimation

Using template matching to estimate local displacements

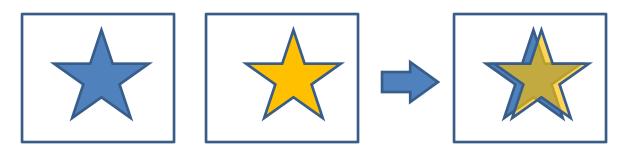

Dense motion estimation

Using optical flow to compute a dense motion vector field

Change Detection

Change Detection

- Detecting an object moving across a constant background
- The forward and rear edges of the object advance only a few pixels per frame

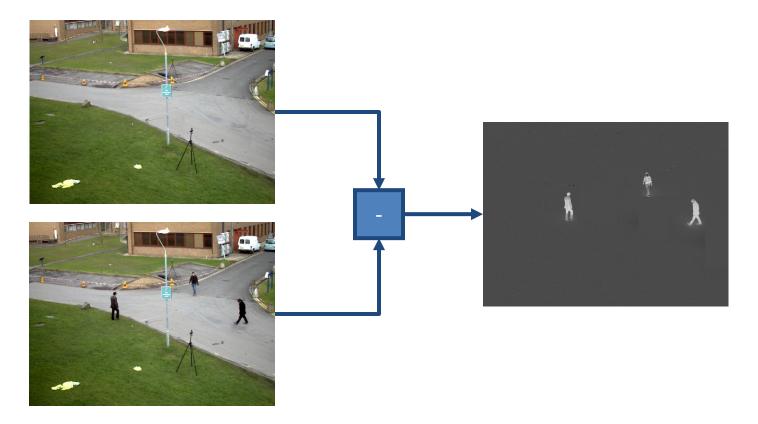

• By subtracting the image I_t from the previous image I_{t-1} the edges should be evident as the only pixels significantly different from zero

Step: Derive a background image from a set of video frames at the beginning of the video sequence

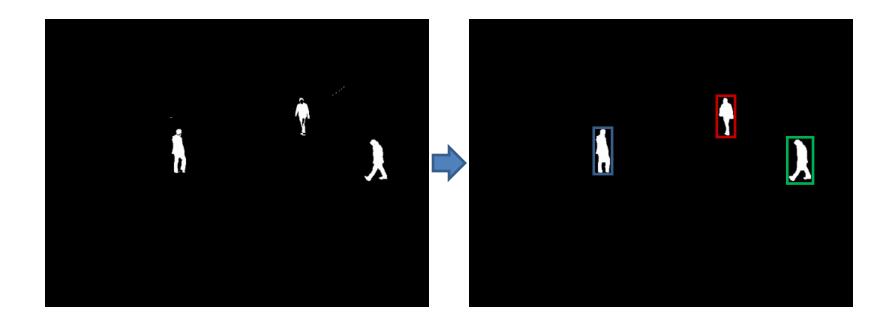

Performance Evaluation of Tracking and Surveillance (PETS) 2009 Benchmark

Step: Subtract the background image from each subsequent frame to create a difference image

Step: Threshold and enhance the difference image to fuse neighbouring regions and remove noise

Detected bounding boxes overlaid on input frame

Change Detection

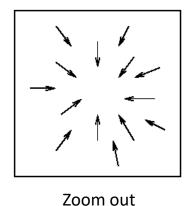

Image subtraction algorithm

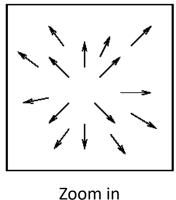

- Input: images I_t and $I_{t-\Delta t}$ (or a model image)
- Input: an intensity threshold τ
- Output: a binary image I_{out}
- Output: a set of bounding boxes B
- 1. For all pixels [r, c] in the input images, set $I_{out}[r, c] = 1$ if $(|I_t[r, c] I_{t-\Delta t}[r, c]| > \tau)$ set $I_{out}[r, c] = 0$ otherwise
- 2. Perform connected components extraction on I_{out}
- 3. Remove small regions in I_{out} assuming they are noise
- 4. Perform a closing of I_{out} using a small disk to fuse neighbouring regions
- 5. Compute the bounding boxes of all remaining regions of changed pixels
- 6. Return I_{out}[r, c] and the bounding boxes B of regions of changed pixels

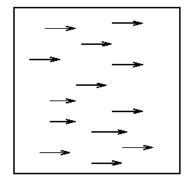

Sparse Motion Estimation

Motion Vector

- A motion field is a 2D array of 2D vectors representing the motion of 3D scene points
- A motion vector in the image represents the displacement of the image of a moving 3D point
 - Tail at time t and head at time t+Δt
 - Instantaneous velocity estimate at time t

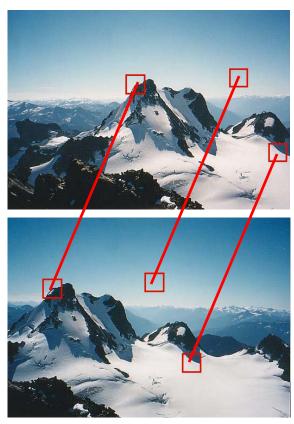

Pan Left

Sparse Motion Estimation

 A sparse motion field can be computed by identifying pairs of points that correspond in two images taken

at times t and t+Δt

- Assumption: intensities of interesting points and their neighbours remain nearly constant over time
- Two steps:
 - Detect interesting points at t
 - Search corresponding points at t+Δt

Sparse Motion Estimation

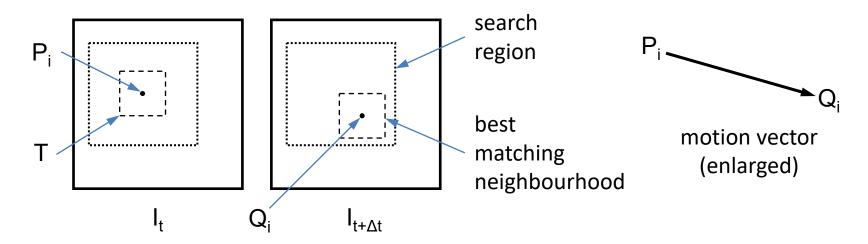

- Detect interesting points
 - Image filters
 - Canny edge detector
 - Hessian ridge detector
 - Harris corner detector
 - SIFT features
 - ...
 - Interest operator
 - Computes intensity variance in the vertical, horizontal and diagonal directions
 - Interest point if the minimum of these four variances exceeds a threshold

Detect Interesting Points

```
Procedure detect interesting points(I,V,w,t) {
    for (r = 0 \text{ to } MaxRow - 1)
        for (c = 0 \text{ to } MaxCol - 1)
            if (I[r,c] is a border pixel) break;
             else if (interest operator(I,r,c,w) >= t)
                 add (r,c) to set V;
Procedure interest operator (I,r,c,w) {
    v1 = variance of intensity of horizontal pixels I[r,c-w]...I[r,c+w];
    v2 = variance of intensity of vertical pixels I[r-w,c]...I[r+w,c];
    v3 = variance of intensity of diagonal pixels I[r-w,c-w]...I[r+w,c+w];
    v4 = variance of intensity of diagonal pixels I[r-w,c+w]...I[r+w,c-w];
    return min(v1, v2, v3, v4);
```

Sparse Motion Estimation

- Search corresponding points
 - Given an interesting point P_i from I_t , take its neighbourhood in I_t and find the best matching neighbourhood in $I_{t+\Delta t}$ under the assumption that the amount of movement is limited

This approach is also known as template matching

Similarity Measures

Cross-correlation (to be maximised)

$$CC(\Delta x, \Delta y) = \sum_{(x,y) \in T} I_t(x,y) \cdot I_{t+\Delta t}(x + \Delta x, y + \Delta y)$$

Sum of absolute differences (to be minimised)

$$SAD(\Delta x, \Delta y) = \sum_{(x,y)\in T} \left| I_t(x,y) - I_{t+\Delta t}(x + \Delta x, y + \Delta y) \right|$$

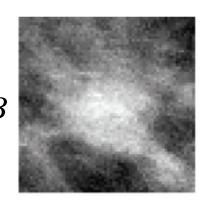

Sum of squared differences (to be minimised)

$$SSD(\Delta x, \Delta y) = \sum_{(x,y)\in T} \left[I_t(x,y) - I_{t+\Delta t}(x + \Delta x, y + \Delta y) \right]^2$$

Similarity Measures

Mutual information (to be maximised)

$$MI(A, B) = \sum_{a} \sum_{b} P_{AB}(a, b) \log_{2} \left(\frac{P_{AB}(a, b)}{P_{A}(a)P_{B}(b)} \right)$$

Subimages to compare:

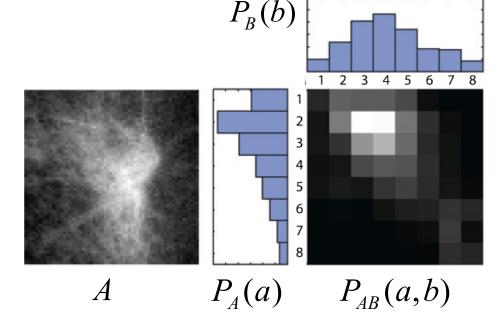

$$A \subset I_t \quad B \subset I_{t+\Delta t}$$

Intensity probabilities:

$$P_{A}(a)$$
 $P_{B}(b)$

Joint intensity probability:

$$P_{AB}(a,b)$$

Dense Motion Estimation

Dense Motion Estimation

Assumptions:

- The object reflectivity and illumination do not change during the considered time interval
- The distance of the object to the camera and the light sources does not vary significantly over this interval
- Each small neighbourhood $N_t(x,y)$ at time t is observed in some shifted position $N_{t+\Delta t}(x+\Delta x,y+\Delta y)$ at time $t+\Delta t$
- These assumptions may not hold tight in reality, but provide useful computation and approximation

Spatiotemporal Gradient

Taylor series expansion of a function

$$f(x + \Delta x) = f(x) + \frac{\partial f}{\partial x} \Delta x + \text{h.o.t} \implies$$
$$f(x + \Delta x) \approx f(x) + \frac{\partial f}{\partial x} \Delta x$$

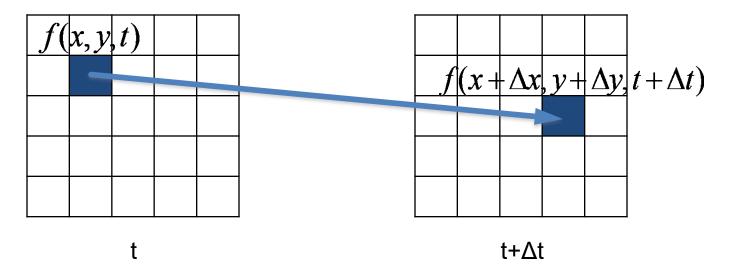

Multivariable Taylor series approximation

$$f(x + \Delta x, y + \Delta y, t + \Delta t) \approx f(x, y, t) + \frac{\partial f}{\partial x} \Delta x + \frac{\partial f}{\partial y} \Delta y + \frac{\partial f}{\partial t} \Delta t$$
 (1)

Optical Flow Equation

Assuming neighbourhood $N_t(x, y)$ at time t moves over vector $V=(\Delta x, \Delta y)$ to an identical neighbourhood $N_{t+\Delta t}(x+\Delta x, y+\Delta y)$ at time $t+\Delta t$ leads to the optical flow equation:

$$f(x + \Delta x, y + \Delta y, t + \Delta t) = f(x, y, t)$$
 (2)

Combining (1) and (2) yields the following constraint:

$$\frac{\partial f}{\partial x} \Delta x + \frac{\partial f}{\partial y} \Delta y + \frac{\partial f}{\partial t} \Delta t = 0 \Rightarrow$$

$$\frac{\partial f}{\partial x} \frac{\Delta x}{\Delta t} + \frac{\partial f}{\partial y} \frac{\Delta y}{\Delta t} + \frac{\partial f}{\partial t} \frac{\Delta t}{\Delta t} = 0 \Rightarrow$$

$$\frac{\partial f}{\partial x} v_x + \frac{\partial f}{\partial y} v_y + \frac{\partial f}{\partial t} = 0 \Rightarrow$$

$$\nabla f \cdot v = -f_t$$

where $v=(v_x,v_y)$ is the velocity or *optical flow* of f(x,y,t) and $\nabla f=(f_x,f_y)=(\partial f/\partial x,\,\partial f/\partial y)$ is the gradient

- The optical flow equation provides a constraint that can be applied at every pixel position
- However, the equation does not have unique solution and thus further constraints are required

For example, by using the optical flow equation for a group of adjacent pixels and assuming that all of them have the same velocity, the optical flow computation task amounts to solving a linear system of equations using the least-squares method

Many other solutions have been proposed (see references)

Example: Lucas-Kanade approach to optical flow

Assume the optical flow equation holds for all pixels p_i in a certain neighbourhood and use the following notation:

$$v = (v_x, v_y)$$
 $f_x = \frac{\partial f}{\partial x}$ $f_y = \frac{\partial f}{\partial y}$ $f_t = \frac{\partial f}{\partial t}$

Then we have the following set of equations:

$$f_{x}(p_{1})v_{x} + f_{y}(p_{1})v_{y} = -f_{t}(p_{1})$$

$$f_{x}(p_{2})v_{x} + f_{y}(p_{2})v_{y} = -f_{t}(p_{2})$$

$$\vdots \qquad \vdots$$

$$f_{x}(p_{N})v_{x} + f_{y}(p_{N})v_{y} = -f_{t}(p_{N})$$

• Example: Lucas-Kanade approach to optical flow The set of equations can be rewritten as Av = b where

$$A = \begin{bmatrix} f_{x}(p_{1}) & f_{y}(p_{1}) \\ f_{x}(p_{2}) & f_{y}(p_{2}) \\ \vdots & \vdots \\ f_{x}(p_{N}) & f_{y}(p_{N}) \end{bmatrix} \qquad v = \begin{bmatrix} v_{x} \\ v_{y} \end{bmatrix} \qquad b = \begin{bmatrix} -f_{t}(p_{1}) \\ -f_{t}(p_{2}) \\ \vdots \\ -f_{t}(p_{N}) \end{bmatrix}$$

This can be solved using the least-squares approach:

$$A^{T}Av = A^{T}b$$
 \Rightarrow $v = (A^{T}A)^{-1}A^{T}b$
